Class 3 — input() Function Notes

What is input()?

The **input()** function is used to take data from the user through the keyboard while the program is running.

Important Point

input() always returns a **string** — even if the user types a number.

```
name = input("What is your name? ")
print("Hello, " + name)
```

Taking Numbers as Input

If you need to do calculations with the input, you must convert it using **int()** or **float()**.

```
age = input("Enter your age: ")
age = int(age) # convert string to integer
print(age + 1)
```

Common Mistake ■

Trying to do math directly on input() without converting it first causes an error.

```
age = input("Enter your age: ")
print(age + 1) # Error! string + int not allowed
```

Quick Reference Table

Concept	Example	Description
Basic input	input("Name: ")	Takes text input from user (string)
Convert to int	int(input("Age: "))	Converts user input into an integer
Convert to float	float(input("Marks: "))	Converts user input into a decimal number

Class Example (Mini Demo)

```
num1 = int(input("First number: "))
num2 = int(input("Second number: "))
print("Sum:", num1 + num2)
```
